Meeting Minutes

61st EDNAP Meeting, Barcelona, Spain, Catalunia Plaza Hotel

12.11.2024

Agenda

09:00	**Welcome**	
	Welcome by the host organization	
	Welcome by EDNAP board	EDNAP board
09:20	**Current EDNAP projects**	
	Methylated DNA and age exercise	David Ballard
	MPS RNA cSNPs exercises 3&4	Cordula Haas
	mtDNA heteroplasmy exercise	Walther Parson
	Discussion on the current EDNAP projects	all
11:00	**Coffee/Tea**	
11:30	**Current EDNAP projects**	
	Paper Exercise on Estimating Biogeographic Ancestry from DNA	Marta Diepenbroek, Chris Phillips & W Parson
	Future EDNAP activities	
	part 2 - Paper Exercise on Estimating Biogeographic Ancestry from DNA	Marta Diepenbroek, Chris Phillips & W Parson
13:00	**Lunch**	
14:00	**Future EDNAP activities**	
	Funding for projects with EDNAP participation	EDNAP Board
	CapCell: EU-project initiative on single cell analysis	Walther Parson, Bo Thisted Simonsen
	Brief round: Publications by projects with EDNAP-participation	All
14:45	**EDNAP topics**	
	Member management	EDNAP Board
	Applications for membership	All
	Online meetings	All
	EDNAP Homepage	EDNAP Board
	New logo for EDNAP? (include the use of ISFG-logo?)	EDNAP Board
15:30	**Coffee/Tea**	
16:00	**Updates from other reserch**	
	The ENFSI ReAct project	Peter Gill
	MitoMetrics	Vania Pereira
	Other ISFG projects, that can be adopted by EDNAP	All
16:45	**Any other business**	
	next EDNAP meeting: Luxemburg 6 May 2025 followed by the ENFSI DNA Expert Working Group meeting 7-9 May 2025	EDNAP Board
	other	
17:00	**Closure of the meeting**	
	Closure of the meeting	EDNAP Board

Summary of the presentations/discussions

Current EDNAP projects

1. **Methylated DNA and age exercise** (David Ballard)

David discussed the age methylation collaborative exercise that was carried out in two parts and has been deferred since the pandemic. He presented a summary of both the data and the challenges associated with turning this data into a publication. There was a discussion regarding whether the PGM results were relevant given the instrument is not in common use anymore, where points were raised that the underlying technology is the same as the S5 and that the difference between laboratories is interesting irrespective of the difference between technologies. It was decided to explore what could be done with the data we have and see how a story could be written with the paper. David said he could not look at this before Christmas but would work on it In January.

2. **MPS RNA cSNPs exercises 3&4** (Cordula Haas)

Cordula summarized the results of parts 3 and 4 of the MPS RNA cSNPs exercise, on body fluid identification and donor association. A draft manuscript was shared with the participants, who provided valuable feedback. The manuscript will be submitted to FSI Genetics before Christmas 2024.

3. **mtDNA heteroplasmy exercise** (Walther Parson)

Walther presented the preliminary results of the mtDNA heteroplasmy exercise, which had been delayed due to the pandemic. A total of 24 participants submitted results for the first part of the exercise, which focused on comparing the detection of point and length heteroplasmy across Sanger, Ion Torrent, and Illumina technologies. The exercise utilized five DNA extracts provided by the organizing laboratory in Innsbruck. While the detection and reporting of point heteroplasmy were generally consistent across the technologies, notable differences were observed in the reporting of length heteroplasmy, both within and between the technologies. These findings may necessitate revisions to the current interpretation guidelines. Walther will share the result tables with the participants, inviting comments and corrections. A manuscript summarizing and presenting the findings will be prepared.

4. **Paper Exercise on Estimating Biogeographic Ancestry from DNA – part 1** (Marta Diepenbroek)

Marta delivered the final report on the joint exercise on biogeographic ancestry (BGA) estimation.

The slides focused on reports provided by the participants of the exercise, by presenting data in a structure aligned with the planned publication. The nine samples used in the study were divided into three groups with varying levels of difficulty: “easy” samples, samples with

similar genetic patterns, and “advanced” samples. Marta provided a summary of how the labs reported the biogeographical ancestry (BGA) of the samples, emphasizing the different approaches participants used. Additionally, she discussed how labs reported phenotype predictions based on the provided HIrisPlex-S p-values.

It was concluded that simple, unequivocal ancestries received consistent and clear reporting across all labs, while complex samples did not. This highlighted a need for guidelines on data interpretation and the use of software such as STRUCTURE. It was also noted that phenotype predictions lacked consistency between labs, despite most using the available HPS guidelines, indicating a need for updated guidelines on phenotype reporting. Marta also discussed the use of uniparental markers for BGA analysis, concluding that the interpretation of both maternal and paternal markers lacks a clear pathway.

Marta presented the proposed structure of the publication summarizing the study, which will include results from the analyses, lab reports, and feedback from questionnaires completed by participants. It was concluded that this publication should play an observational role. The manuscript is planned for submission before the next EDNAP meeting in May 2025.

Future EDNAP activities

1. **Paper Exercise on Estimating Biogeographic Ancestry from DNA – part 2** (Marta Diepenbroek)

Marta introduced the idea of a follow-up study, primarily planned based on feedback gathered during the first exercise. In this study, a smaller number of samples (five) will be used, and based on an updated ethics committee agreement, raw data (genotypes and haplotypes) will be sent to the participants. Marta shared that guidelines on using STRUCTURE, Snipper, Genogeographer, as well as on interpreting X-SNPs and uniparental markers, will be provided to the participants. In the study, labs will be able to choose which set of markers they will receive and decide how they want to conduct the data analysis. The proposal was positively received by the meeting participants. The follow-up study is planned to begin in 2025.

2. **CapCell** (Bo Thisted Simonsen and Walther Parson)

The EDNAP Board facilitated discussions on potential future activities. Bo and Walther introduced the CapCell consortium, which has applied for EU funding under the current Open Call HORIZON-CL3-2024-FCT-01. If successful, the consortium will focus on developing methods, software, and interpretive frameworks for single-cell forensic DNA analysis. EDNAP, represented by Bo, will support the consortium by reviewing research plans and achievements.

EDNAP Topics

1. **Member management**: Bo Thisted Simonsen summarized the Board's considerations regarding member management. The Board recommended retaining all current members who have attended meetings within the past five years. Applications for new memberships will be reviewed and voted for during (online) meetings. Former members who have not attended meetings in the past five years may reapply for membership. The boards considerations on member management was approved.
2. **Applications for membership**: There were two applications for membership, Natalie de Jong-Weiler, The Netherlands (presented by Walther Parson) and Andreas Tillmar, Sweden (presented by Bo Thisted Simonsen). Both applications were unanimously approved.
3. **Online meetings**: The group discussed the option of online meetings. It was decided that online meetings can be held on an *ad hoc* basis in addition to the annual personal meetings.
4. **EDNAP homepage**: The EDNAP homepage, which is part of the ISFG website, is scheduled for an update. As part of this process, the EDNAP homepage will also undergo revisions.
5. **New EDNAP logo**: There was a brief discussion, no decision was made.

Updates from other research

1. **The ENFSI ReAct project** (Peter Gill)

Peter provided a summary for the ENFSI supported ReAct project, which is an inter-laboratory study to investigate direct and indirect transfer using an agreed experimental design. The first paper is now published as a pre-print and is complemented by databases and software to calculate likelihood ratios. There were wide differences in DNA recovery which affects the likelihood ratios. The ReAct II project is designed to address the issues of reproducibility between labs, by introducing a method to measure DNA recovery. These data will be used to update ReAct I project results.

2. **MitoMetrics** (Vania Pereira)

Vania Pereira presented MitoMetrics - an initiative that aims to address challenges when interpreting forensic mtDNA evidence. The work has a particular focus on heteroplasmy and mtDNA profile discrepancies when comparing different tissues from the same donor. The study introduced a preliminary model to calculate the weight of mtDNA-based evidence using a likelihood ratio approach that accounts for profile discrepancies between tissues.

Participants

Last Name	First Name	Contact E-mail	Institution
Aili Fagerholm	Siri	siri.aili-fagerholm@polisen.se	National Forensic Centre, Swedish Police Authority

Evolution of EDNAP

EDNAP meeting 12.11.2024

Cordula Haas, Bo Simonsen, Walther Parson

History of EDNAP

1988: Foundation of EDNAP with the aim of harmonizing DNA technology for crime investigation by organizing collaborative intercomparison exercises

1991: EDNAP was accepted as a working group of the International Society for Forensic Genetics (ISFG)
Each European country is represented by one laboratory

First collaborative exercises on:
single-locus DNA probes
STR typing > led to the selection of the "European standard set of loci"

1997-2000: STADNAP network > exercises on autosomal and Y-STRs, mtDNA

1999: The EDNAP Forensic mtDNA Population Database EMPOP was established

Since 2004: joint meetings with the DNA Expert Working Group of the European Network of Forensic Science Institutes (ENFSI)

Recent collaborative exercises on:
single nucleotide polymorphism (SNP) typing
identification of body fluids in forensic stain samples using mRNA analysis
forensic ancestry analysis by SNP typing
forensic phenotyping of eye colour
age estimation by measuring DNA methylation of informative CpG DNA nucleotides

33 EDNAP publications

Here the 5 most recent ones:

Ingold S, Dørum G, Hanson E, Ballard D, Berti A, Gettings KB, Giangasparo F, Kampmann ML, Laurent FX, Morling N, Parson W, Steffen CR, Ulus A, van den Berge M, van der Gaag KJ, Verdoliva V, Xavier C, Ballantyne J, Haas C. New directions of EDNAP

Today, forensic genetic typing methods are well-established and harmonized in Europe and other parts of the World. The EDNAP laboratories perform accredited DNA analyses. Most EDNAP laboratories are members of the DNA Expert Working Group of ENFSI, which serves as a platform for practical scientific collaboration among European forensic genetic laboratories. The ENFSI group competently addresses many of the issues initially dealt with by EDNAP.
> The need for EDNAP's role in harmonizing standard DNA typing methods no longer exists, a lot of overlap with ENFSI

EDNAP is undergoing a transformation and in this context has adopted Terms of Reference and Statutes for EDNAP. The main points are:

Aims:
- share information, explore new research areas, and drive the development of forensic genetics
- organize collaborative exercises, workshops, in-depth discussions

Members:
- change from laboratory/country membership to individual/personal membership
- the General Assembly decides on membership with a simple majority
- invite guests (temporary)

Meetings:
- at least one annual personal scientific meeting, together with ENFSI
- additional personal, internet-based, or combined meetings

Projects:
- explore new forensic genetic research areas suitable for research projects
- form research groups
- apply for funding

New directions of EDNAP

New structure and organization of EDNAP:
- is a working group with its own statutes under the International Society for Forensic Genetics
- is organized with an elected board with a Chairman, a Deputy Chairman, a Secretary/Treasurer

At the last EDNAP meeting (29. May 2024 in Copenhagen)
- the Statutes and the terms of references (ToR) were adopted
- new EDNAP board members were elected
  Chair: Cordula Haas
  Deputy Chair: Bo Simonsen
  Secretary and Treasurer: Walther Parson

New directions of EDNAP

Change of collaboration style:

- Colleagues that have new research questions/suggestions can get in contact with the EDNAP group directly/immediately
- Colleagues that plan to present ongoing exercise results should send results well ahead of the meeting to allow for more meaningful discussions
- Particularly problems, limitations that arise during the analyses should be shared when they arise to allow for better troubleshooting

Focus more on EDNAP members' practical experiences (at court)

On-going collaborative exercises:

- Paper Exercise on Estimating Biogeographic Ancestry (M. Diepenbroek, C. Phillips & W. Parson)
- mtDNA heteroplasmy exercise (W. Parson)
- Second exercise on methylated DNA and age (D. Syndercombe Court, D. Ballard)
- Exercise 4 on mRNA typing with MPS (C. Haas)
- The series of exercises relating to DNA transfer (R. van Oorschot, B. Kokshoorn)

→ New topics/ideas are welcome ☺!

New agenda structure

Preliminary EDNAP Agenda

Methylated DNA & Age Exercise

David Ballard

EDNAP, Barcelona 2024

KING'S College LONDON

EDNAP Exercise

- 15 laboratories participated
  - 8 MiSeq only
  - 5 PGM only
  - 2 MiSeq and PGM/S5
- Part 1 - 7 Methylation standards between 0-100% sent out to all labs
- Part 2 – 7 blood stains sent out to laboratories to test. Also optional submission of extra blood samples. Age prediction by ANN from methylation values at 12 markers.

Introduction

The development of methods that can accurately estimate an individual's chronological age from trace evidence is an ongoing quest in the field of forensic DNA intelligence. The retrieval of this information, as well as information regarding externally visible characteristics, like eye, hair or skin colour and hair morphology [1-4], from DNA samples recovered from crime scenes, can significantly aid police investigations, especially in cases lacking eye witness testimonies and/or intact human remains.

While multiple biomarkers for chronological age have been suggested over the years [5-19], the quantification of DNA methylation, an epigenetic modification that mainly affects cytosines when these are followed by guanines in a 5'->3' direction and is a known modulator of genetic expression [20], has been the focus of recent research. The main reasons behind this choice are the strong and specific correlation of multiple methylation sites with chronological age, as shown in multiple studies [20-24], as well as methylation's biological stability over time [24-28].

Several different approaches have been established for the quantification of DNA methylation, with the four main ones being (i) massively parallel sequencing (MPS), (ii) pyrosequencing, (iii) methylation SNaPshot and (iv) MALDI-TOF mass spectrometry (EpiTYPER). Massively parallel sequencing offers high sensitivity as well as single-base resolution and is able to cope with large scale multiplexing, characteristics that place it to the top of the choices for DNA methylation quantification for forensic purposes. Furthermore, forensic laboratories worldwide are becoming increasing familiar with this technology as it has been applied to multiple aspects of forensic analysis [29-33]. The most common MPS instrumentations currently being used in forensic laboratories include the MiSeq (Illumina), MiSeq FGx (Verogen) and the ION Personal Genome Machine (ION PGM) and ION S5 systems (Life Technologies).

Recent publications reveal significant scientific leaps towards making age estimation through DNA methylation a reality for forensic casework, with the developed methods showcasing promising results in terms of accuracy, robustness and sensitivity [34-37]. However, even though few published methods have been successfully reproduced across the forensic community [38, 39] little research has been conducted on the transferability of the proposed methods between different laboratories as well as different instruments. While the stages of identification of promising markers and optimisation of the potential methods are vital to the development of new forensic tools, transferability between different forensic facilities is also an important factor that needs to be investigated, especially when the proposed methods involve high cost equipment like the MPS instrumentation.

In order to investigate further into this matter, this exercise focuses on the transferability of a previously described DNA methylation-based age prediction method originally developed on the MiSeq FGx platform [40]. The same protocol, with minor instrument-related alterations was performed in 14 different labs using different types of MPS technology including the MiSeq, MiSeq FGx, ION PGM and ION S5 systems and the results were compared both for standards of known methylation and real samples.

Materials and Methods

DNA methylation standards

For the first part of this study 7 pre-mixed methylation standards ranging from 0% to 100% methylation were purchased from EpigenDx (Massachusetts, USA) at a concentration of 50ng/µL. Standards were diluted and delivered to the participating laboratories at a final concentration of 2.5ng/µL.

Sample Collection

For the leading research group of this exercise in King's College London, sample collection for this study was performed under ethical approval granted by the Biomedical Sciences, Dentistry, Medicine and Natural & Mathematical Sciences Research Ethics Subcommittee (BDM/13/14-30). A total of 7 donors aged between 27.7 and 79.7 years were recruited for the collection of whole blood samples (samples A-G) via venepuncture following the acquisition of full informed consent. Samples were stored at 4°C.

Sample Shipping

Methylation standards were shipped to the participating laboratories in sealed 1.5mL snap-top containers, while samples A-G were shipped in the form of blood stain cards.

DNA Extraction and Quantification

Genomic DNA was extracted by different methods depending on the laboratory, with the BioRobot®EZ1 automated purification instrument (Qiagen, Hilden, Germany) in combination with the EZ1 Blood and Investigator kits being the most popular choice. Other methods included the QIAamp DNA mini kit (Qiagen, Hilden, Germany), QIAamp DNA Investigator kit (Qiagen, Hilden, Germany), DNA IQ system (Promega Corporation, Wisconsin USA), Wizard® Genomic DNA Purification kit (Promega Corporation, Wisconsin USA), PrepFiler Forensic DNA Extraction kit (Thermo Fisher Scientific, Massachusetts, USA), Chelex and organic extraction (Supplementary File 1a).

Similarly, several different methods were employed for the quantification of the DNA extracts with the most common ones being a fluorometric quantitation using Qubit for double stranded DNA high sensitivity (Thermo Fisher Scientific, Massachusetts, USA) and a real-time PCR quantitation with Quantifiler® Trio DNA Quantification kit (Thermo Fisher Scientific, Massachusetts, USA) in full or half volumes. Additional methods included the Quantifiler® Human DNA Quantification (Thermo Fisher Scientific, Massachusetts, USA), Quantifiler® Duo (Thermo Fisher Scientific, Massachusetts, USA), Quantifiler® Human Plus (Thermo Fisher Scientific, Massachusetts, USA), AluQuant™ Human DNA Quantitation (Promega Corporation, Wisconsin USA), Quantus™ Fluorometer in combination with the QuantiFluor™ dsDNA Dyes (Promega Corporation, Wisconsin USA) and NanoDrop Spectrophotometer (Thermo Fisher Scientific, Massachusetts, USA) (Supplementary File 1b).

3. Results

3.1 *DNA standards of known methylation*

In the first part of this collaborative exercise, the different laboratories were provided with the same pre-mixed primers as well as the same pre-mixed DNA methylation standards ranging from 0 to 100% methylation. All standards were analysed in duplicate by each participant laboratory and the detected methylation values were averaged across the labs using MiSeq technology and those using Ion PGM or Ion S5 sequencers (Fig.1). While results showed good correlation between the two different sequencing technologies for 7/12 markers, significant differences ($p<0.05$) were observed for cg04528819, cg22736354 and cg06493994.

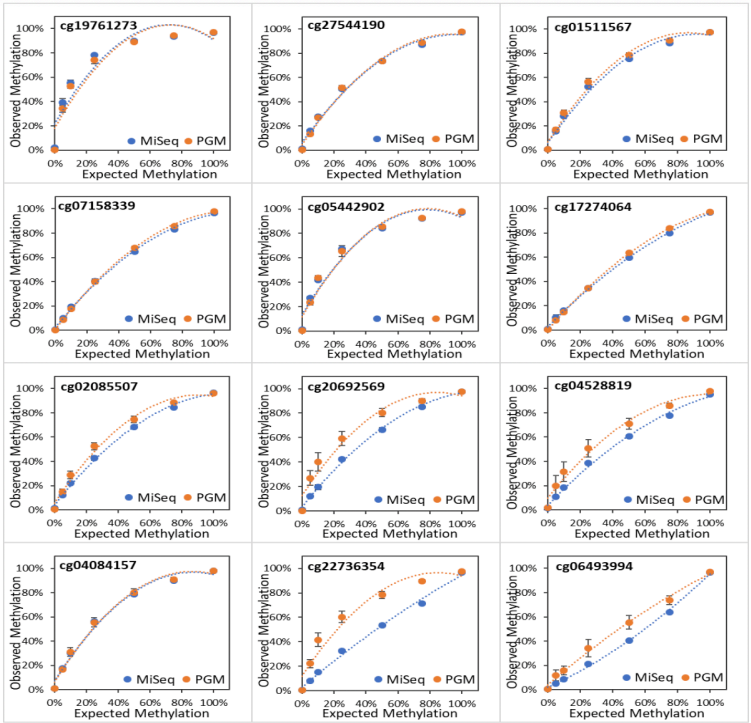

Figure 1. Averaged detected DNA methylation values for the 7 standards of known methylation for the laboratories using MiSeq (blue) and PGM/S5 (orange) technology. Significant differences were observed for cg04528819,

- Average sequencing reads for the different markers in the MiSeq and the PGM/S5 platforms. Error bars represent the standard deviation.

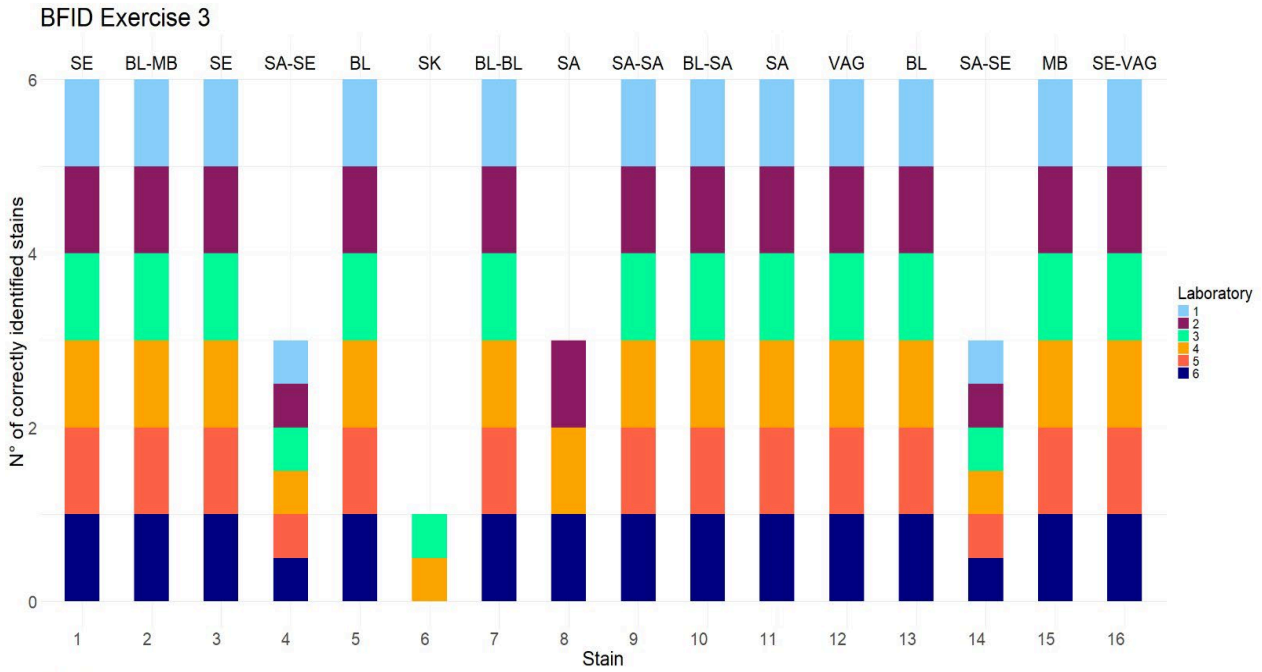
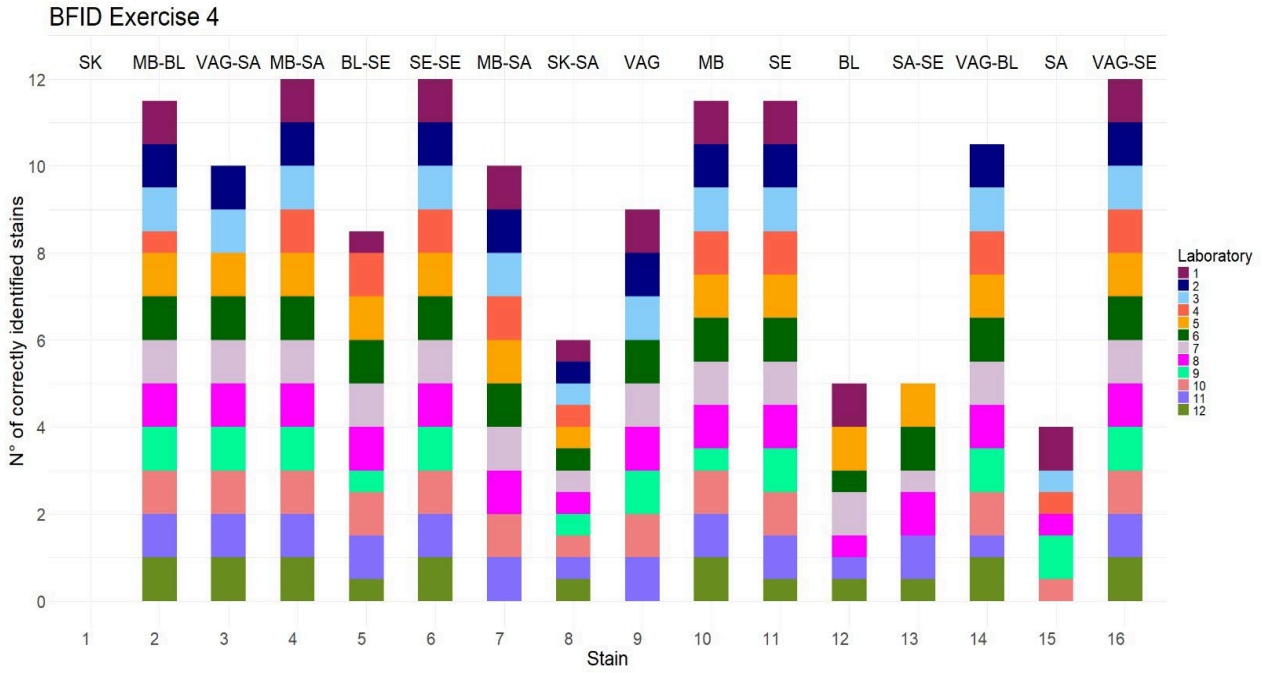
Feedback from participants

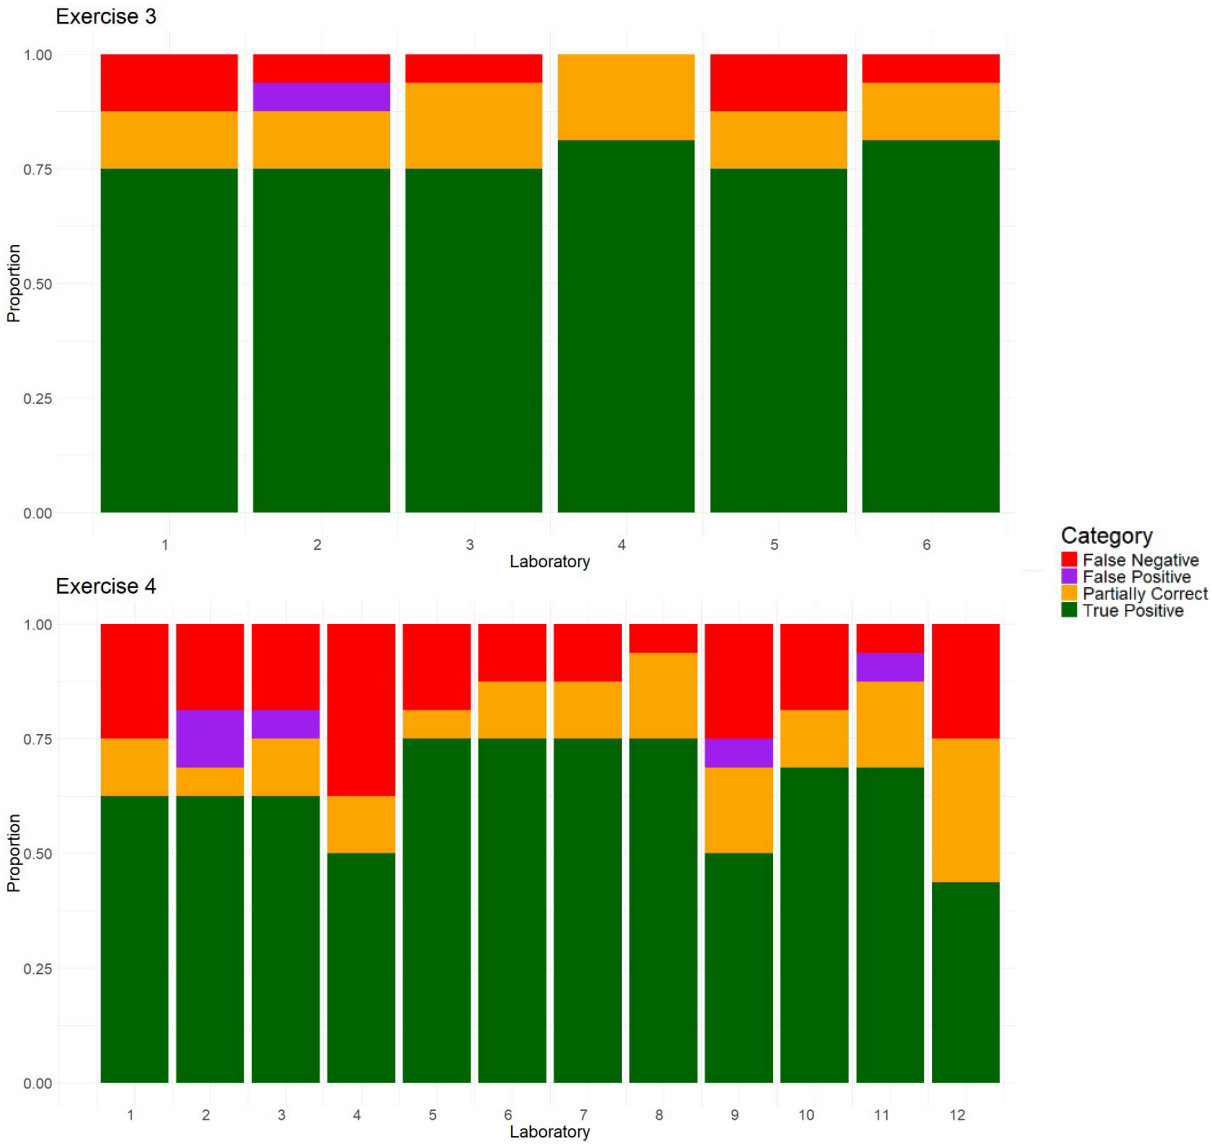
- well organized exercise, great opportunity for us to get some hands on practice on mRNA sequencing, monster task (different labs, different knowledge, different sequencers, different panels, two different exercises - hats off)
- very nice manuscript, really nice work, we are impressed, great job and not an easy task, well structured, super introduction – very nice overview
- too many “detours” > focus on main story
- Main suggestions:
  - performance by laboratory
  - thresholds / cross-reactions / false positives
  - presentation of cSNP results

The number of laboratories that correctly identified one or more body fluid components

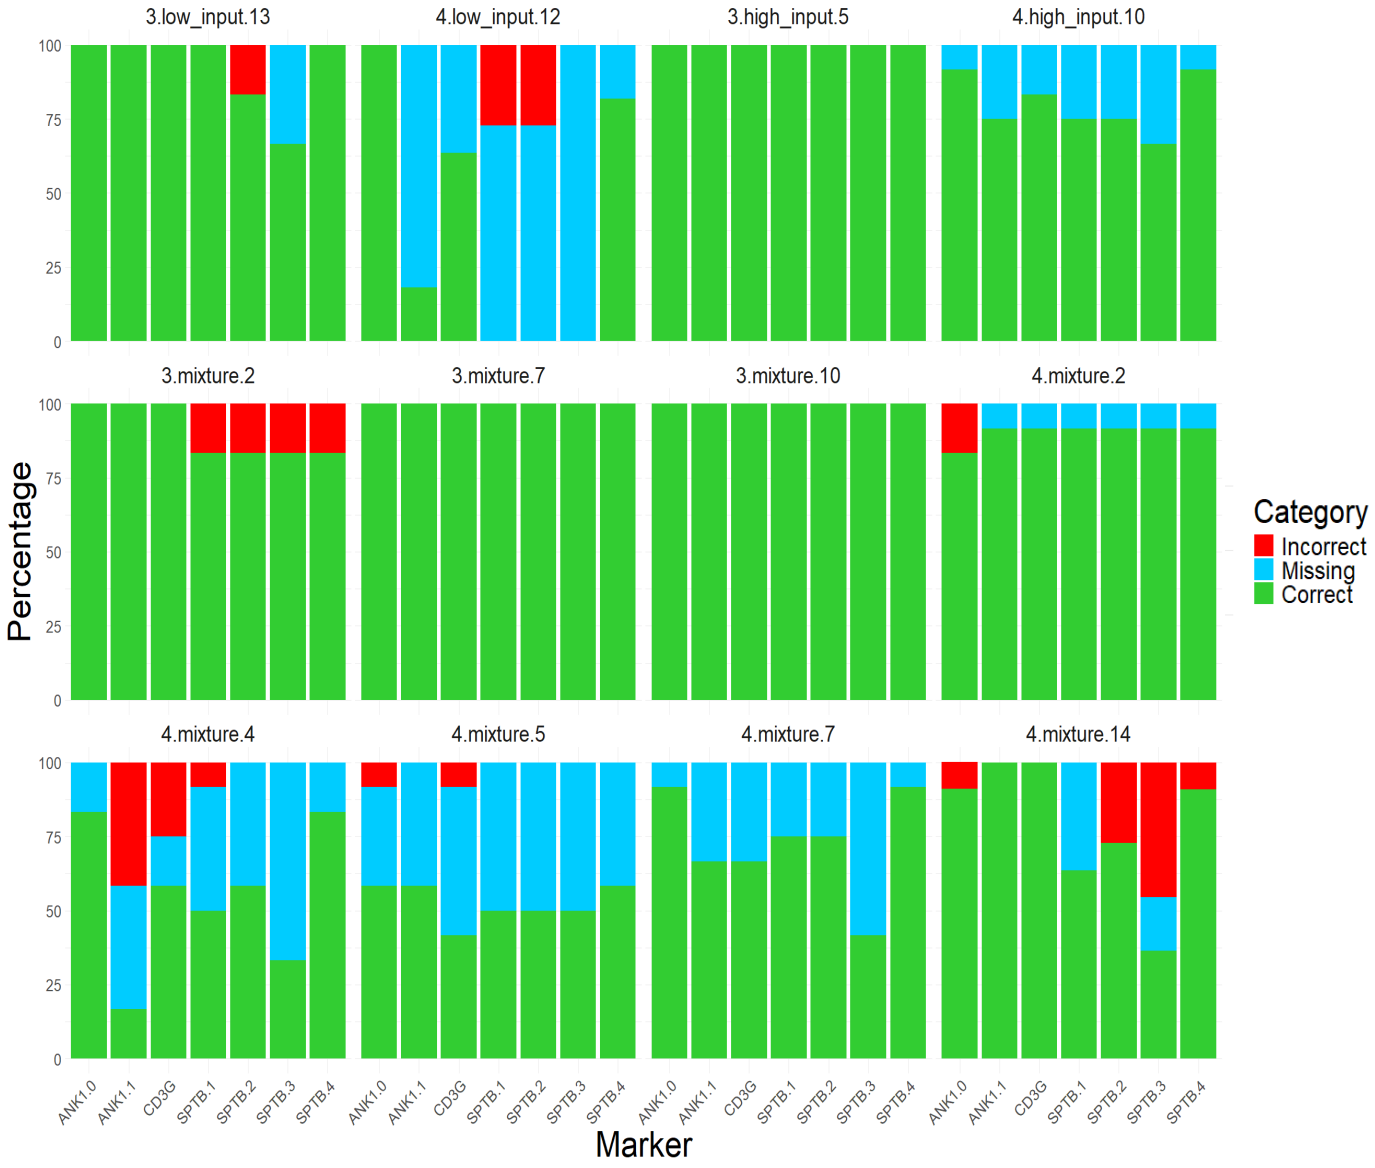




Proportions of false negatives, false positives, partially correctly predicted stains and true positives



Percentage of blood cSNP genotypes found in the respective categories (correct/missing/incorrect) per stain



The number of full cSNP profiles identified by the participating laboratories in each exercise per stain and per body fluid component

1. Introduction

- mRNA profiling has emerged as a promising technique for body fluid identification (BFID)
- Coding region SNPs within body fluid specific transcripts facilitate the association between a body fluid and its donor
- Two RNA BFID-cSNP-assays have been developed[1]:
  - the BSS-cSNP-assay for BFID of all forensically relevant body fluids and skin, incl. cSNPs for blood, saliva and semen
  - the 6F-cSNP-assay for BFID incl. cSNPs for blood, saliva, semen, vaginal secretion, menstrual blood, and skin
- Each BFID-cSNP RNA assay comes with a concomitant DNA-cSNP assay for donor genotyping

2. Principle of the Method

Assigning a body fluid to a donor is a three-step-process:

- STR analysis to obtain the number of contributors
- mRNA profiling to determine the body fluid(s) present
- Comparison of the DNA and RNA cSNP genotypes

3. Aims

In two consecutive collaborative exercises organized by the Zurich Institute of Forensic Medicine (ZIFM), both BFID-cSNP assays were evaluated with respect to the following aspects:

- The robustness and reproducibility across different laboratories using two sets of stains provided by the ZIFM:
  - 6 participating laboratories in exercise 3
  - 12 participating laboratories in exercise 4
- The performance on stains prepared by participants (own stains)
- The effect of different sequencing platforms

4. EDNAP mRNA MPS Exercises

The EDNAP exercises 3 and 4 entailed the analysis of:

- 16 provided stains (single source and/or mixed, Tables 1 + 2)
- 8 own stains (single source and/or mixed) incl. the respective DNA reference profiles (results not shown)
- Participating laboratories were given detailed instructions for stain analysis
- All the data from the participating laboratories was collected and analysed at the ZIFM.

5. Laboratory Workflow

References

1. Hanson, Erin, et al. "Targeted S5 RNA sequencing assay for the identification and direct association of common body fluids with DNA donors in mixtures." *International journal of legal medicine* 137.1 (2023): 13-32.

6. Results

- Sequencing results were compared among participants (Fig. 1)
- Stain compositions were predicted by considering the proportion of body-fluid-specific markers:
  - 13/16 correctly predicted stains in exercise 3
  - 11/16 correctly predicted stains in exercise 4
- Sequencing results were compared across platforms in exercise 4 (Fig. 2)
- The cSNP genotypes were compared to the DNA reference profiles to associate body fluids with their donors (Table 3)

Abbreviations:
BF/T stands for body fluid/tissue, BL for blood, MB for menstrual blood, SA for saliva, SE for semen, VAG for vaginal secretion, and SK for skin.

Stain N°	BF/T	Amount	Stain Provided
1	SE	10 µl	piece of fabric (boxer shorts)
2	BL-MB	1/2 Swab + 25 µl	1/2 swab
3	SE	50 µl	artificial cotton
4	SA-SE	50 µl + 25 µl	part of a T-shirt
5	BL	50 µl	1 swab

Table 3: Example for donor association of a provided stain (stain 3, exercise 4, SA-VAG). DNA cSNP genotypes (donors 1 and 2) in the markers of interest are compared to the RNA cSNP genotypes (results of three exemplary laboratories, no results reported for CYP2A6). The matching donors for the identified body fluids are marked in light blue.

7. Conclusion

- Very promising results, i.e. the majority of the stains in both exercises were typed correctly
- Results were quite consistent across different laboratories
- The 6F-BFID-cSNP assay performed well on both sequencing platforms
- Laboratories with limited RNA experience also reported good results
- For body fluid identification difficulties arise because of various misleading reads:
  - If a stain has low reads in general, reads in target markers are low as well → harder to interpret
- Performance of the association of a body fluid and a donor is dependent on how many markers are detected per body fluid:
  - Not every marker includes a cSNP with the power to exclude a donor

Summary

- Overall promising results with both assays
- Some participants did not (fully) follow the recommendations
- Laboratories with limited RNA experience also achieved good results
- Results were quite consistent across different laboratories
- The cSNP panels performed well on both sequencing platforms
- Comparison with Cologne cSNP panel (30 body fluid markers, 70 cSNPs)

➢ Manuscript will be submitted to FSI Genetics soon

Challenges

Some laboratories sent results back with significant delay (covid, etc …)

Reporting of heteroplasmy not uniform

Huge diversity of individual platforms (= instrumentation + software) introduced additional variability

Developed agnostic software “MPSAligner” to remove variability due to different software (versions) used

Staff change at GMI that required a new person to pick up the work

Results DNA extracts - Heteroplasmy

Evaluated data in two forms

1) reported results

2) reviewed results

Review: MPSAligner accepts bam files and performs phylogenetic alignment according to ISFG guidelines

=> alignment specific to human mtDNA

MPSAligner is based on the EMPOP query engine SAM2 (Huber et al 2018) that uses rCRS-coded mitotypes/fasta-like data as source

Results DNA extracts – Point Heteroplasmy

Conclusions

Reported and reviewed levels of PHP comparable to each other

Little variation between platforms and instruments

Keep in mind that PHP levels can be affected by primer sequences, which needs to be taken into account in data analysis

Results DNA extracts

Length heteroplasmy (LHP)

Participants were asked to determine and report LHP according to their established guidelines

Most labs reported the **dominant variant** (= major molecule) as recommended by revised ISFG guidelines (Parson et al 2014)

Results – DNA extracts

Reporting of LHP in DNA extracts not concordant between technologies and labs

In total we discern three sources of variation: **technological, software** and **interpretational**

MPSAligner removes individual user settings and variation in software but still results in **LHP differences** between labs

It maybe difficult if not impossible to achieve consistent results across labs (see also Sturk-Andreaggi et al 2020)

Needs to be reflected in interpretation guidelines

Will guide interpretation of results in hair shafts (follow up study)

Way forward

Share tables with participants to confirm data and add missing information

work on manuscript on DNA extracts

evaluate hair results based on platform-specific findings of this study

Quo vadis, BGA?

A collaborative EDNAP exercise on estimating biogeographic ancestry from the DNA of unknown samples

Final update

Organized by:

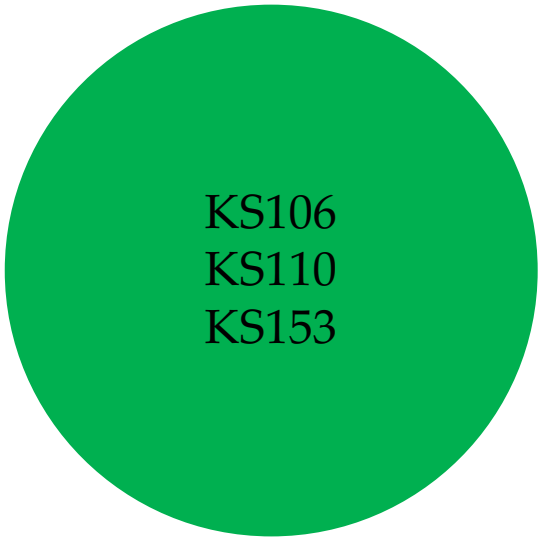
MEDIZINISCHE UNIVERSITÄT INNSBRUCK

LMU LUDWIG-MAXIMILIANS-UNIVERSITÄT MÜNCHEN

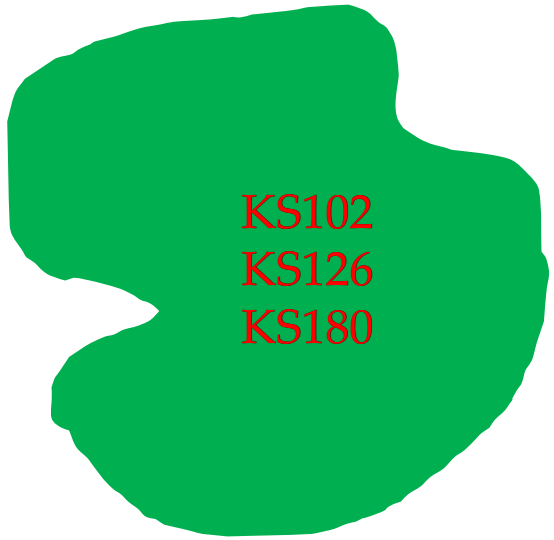
USC UNIVERSIDADE DE SANTIAGO DE COMPOSTELA

Samples

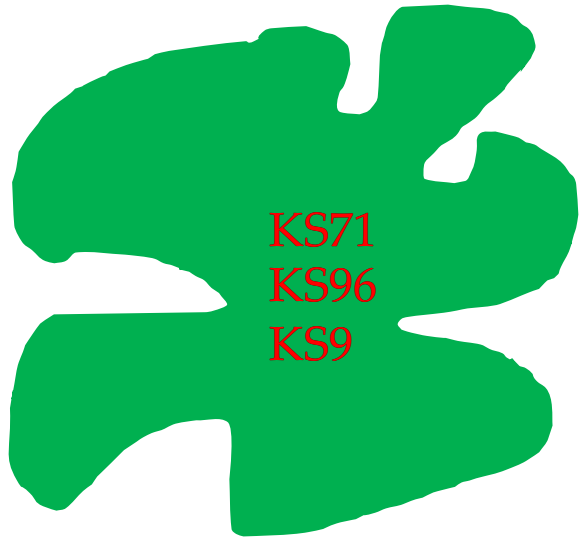
Level 1 – „easy“ samples



Level 2 – samples with similar genetic pattern



Level 3 – „advanced“ samples



Which individual's data did you find the most difficult to analyse?

HPS guidelines: brown/dark brown hair (natural: dark brown)

„brown/dark brown hair“
– 5 labs, 4 with HPS and *1 with updated guidelines*

„brown hair“
- 1 lab, HPS guidelines

„light hair shade and brown to blond hair “
– 1 lab, HPS guidelines

„dark blond or brown hair“
– 1 lab, updated HPS guidelines

„blond or brown hair“
– 1 lab, updated HPS guidelines

Summary

- simple unequivocal ancestries – consistent clear reporting among all labs

- eye colour based on highest p-value consistent among all labs: predictions tend towards the more secure binary classification approach: i.e., blue vs brown, or neither
- hair and skin colour more ambiguous when close and below 0.7
- HPS guidelines tend to ‚darken' European hair colour predictions in comparison to updated guidelines used by some labs
- no consistency between labs that claimed to use HPS guidelines

Haplogroup U7 [edit]

Haplogroup U7 is considered a West Eurasian–specific mtDNA haplogroup, believed to have originated in the Black Sea area approximately 30,000 years ago.[67][114][115] In modern populations, U7 occurs at low frequency in the Caucasus,[115] the western Siberian tribes,[116] West Asia (about 4% in the Near East, while peaking with 10% in Iranians),[67] South Asia (about 12% in Gujarat, the westernmost state of India, while for the whole of India its frequency stays around 2%, and 5% in Pakistan),[67] and the Vedda people of Sri Lanka where it reaches it highest frequency of 13.33% (subclade U7a).[117] One third of the West Eurasian-specific mtDNAs found in India are in haplogroups U7, R2 and W. It is speculated that large-scale immigration carried these mitochondrial haplogroups into India.[67]

KS126 - ancestry results

colour code EU/ME/SA admixture EU/ME admixture co-parentage

Assigned as of European, Middle East and South Asian admixture (4 labs used all markers, *4 only biparental*), examples:

- „admixed (Europe & Middle East & South Asia)“
- „either an admixed individual of European, Middle East and South Asian origin or stems from an admixed population“
- *„more likely if the investigated DNA comes from an individual of European and Middle Eastern genetic admixture, of European and South Asian genetic admixture or of Middle Eastern and South Asian genetic admixture than if the investigated DNA comes from an individual from the European, Middle Eastern, East Asian, South Asian, Oceanian, Native American, or African reference populations“*
- *„biogeographical ancestry being Europe or Middle East or South Asia, or a population with European or Middle East or South Asian ancestry, or an admixture of the aforementioned meta-populations“*

Assigned as of European and Middle East admixture (2 labs used all markers):

- „ancestry is either Middle Eastern, or admixed with a major European component“
- „double inclusion biogeographic ancestry with two root populations, 54.87% European and 44.45% Southwest Asia“

Referred to co-parentage (2 labs used all markers):

- „probably has a mixed biogeographical background a European (probably paternal) - Middle Eastern (probably maternal) origin“
- „under the unadmixed scenario, ancestry in the Middle East or Europe. under the admixed scenario, the results are suggestive of paternal ancestry in Eurasia and maternal ancestry that could be in Europe, Middle East or South Asia “

Summary

- ET gave the clearest STRUCTURE patterns for KS102 (Albanian) and K126 (Turkish) samples in terms of relative EUR-ME proportions
- KS180 (German-Turkish) had incorrect EAS cluster with ET
- KS180 and KS126 respectively, gave PT and BT >0.15 SAS clusters

- differences appeared between KS126 (Turkish) and KS102 (Albanian) in how interpretations were made and how they were reported
- KS126 with stronger ME-SAS description in most reports: consistent in saying the individual was not completely European
- KS180 (German-Turkish) is the first sample where more labs distinguishing the paternal and maternal lineages and commenting on co-parentage

- tendency to over-emphasise relatively small co-ancestry proportions - no guidelines were given by us for the interpretation of minor co-ancestry cluster membership proportions

- the lack of any differentiation of ME-SAS with EUR for the ET X-chromosome SNP set was not explained to participants – data might have been misread

KS9 - ancestry results

KS9 - ancestry results

colour code: no report | AFR/ME/SEA admixture | AFR/ME admixture

Didn't assign to any reference population (*3 labs used only biparental*, 1 all markers), examples:

- *„the biogeographical origin of this individual could not be predicted"*
- *„not possible to find a most likely reference population or most likely genetic admixture for this sample"*

Assigned as African, Middle Eastern and SouthEast Asian admixture (4 labs used all markers), examples:

- „likely that the sample belongs genetically to the African, Middle Eastern and SouthEast Asian admixture population. It is likely that the maternal linage of the sample comes from SouthEast Asia"
- „predominant biogeographical origin is Middle Eastern or African, but in the maternal line an South East Asian origin is most likely (since autosomally East Asian is not strongly represented, this may be a deeper maternal ancestry). There is indication of admixture although a population in between that is not represented in the reference samples cannot be excluded"

Referred to phenotype prediction (1 lab used all markers):

- „either ancestry from the North-east African/Middle-East area or admixed ancestry with male ancestry from Africa and ancestry on the female side from somewhere in the Middle East/South Asia/South-East Asia region. Given the dark-to-black skin tone, the admixed ancestry option is the most likely"

Assigned as of African and Middle East admixture (2 labs used all markers, *1 only biparental*), examples:

- *„biogeographical ancestry being Middle East or Africa, or a population with Middle East or African ancestry, or an admixture of the aforementioned meta-populations"*
- „likely to have a mixed biogeographical background with a dominant African - Middle Eastern origin"

„brown eyes, dark brown / black hair and dark to black skin“

Summary

- KS71: parental admixture STRUCTURE patterns were straightforward for all
- 50% reported uniparental maternal EAS, paternal EUR and 50% reported just admixture
- HIrisPlex-S skin colour test is focussed on EUR, so EAS components produced a dark prediction, highlighting the European-centric SNP selection in this SNP assay

- KS96: produced the most variation in reporting, from the specific: paternal parent EUR, maternal parent AFR, to "only can exclude EAS-OCE-AMR"
- Mito reporting suggests labs are taking EMPOP output without including the qualification that much of the 'global diaspora' distribution of AFR variation which should be necessary to include

- KS9: only sample where many labs refused to make any ancestry prediction
- the most complex patterns of genetic ancestry and consequent interpretations based on which panel, reference sets and software is used

- KS71 and KS9: FDP fully consistent - all probabilities over 0.7
- KS96: first sample where FDP had variable interpretation of the skin colour probabilities

What we learned from you

Which method of biparental SNP analysis did you find the most informative?

STRUCTURE
PCA
GenoGeographer
Converge

Did you find any of the data provided confusing and/or difficult to interpret?

PCA for admixed
BGA more difficult than phenotype
contradictory results
admixed samples
GenoGeographer
STRUCTURE
PCA lacking quantitative metrics

Which individual's data did you find the most difficult to analyse?

71
126
102
9
96
180

Did you refer to the HPS authors' guidelines or did you interpret the provided p-values using your own criteria?

HPS guidelines
own or both

Which additional markers besides the biparental SNPs were most useful for interpreting the data?

mtDNA
X-SNPs
Y-SNPs

Did the provided phenotype predictions have an impact on your conclusions regarding the biogeographic origin of the studied individuals?

no
somewhat

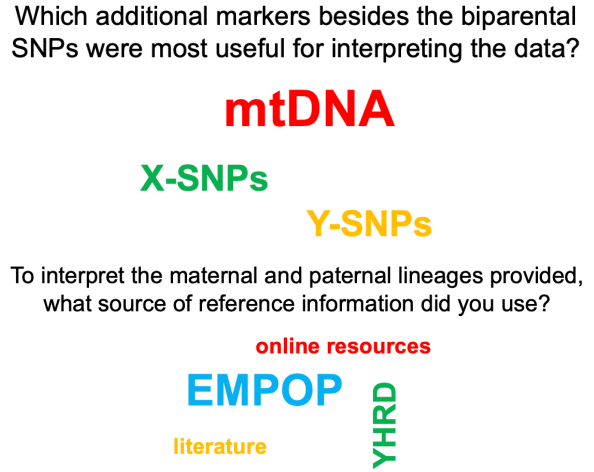
To interpret the maternal and paternal lineages provided, what source of reference information did you use?

online resources
EMPOP
YHRD
literature

Legend: the bigger words reflect the more common replies

General summary

- consistency of genetic patterns between the three autosomal MPS panel's data is important for participants confidence in reporting ancestry, especially when complex
- updated guidelines concerning phenotype reporting are needed
- guidelines concerning usage of common tools like STRUCTURE, SNIPPER and GenoGeographer are needed
- guidelines concerning interpretation of X-SNPs from ET are needed
- Y interpretation lacks a clear path - YHRD was the most common Y search system used, but it is not particularly informative for Y-SNP variation
- similar with EMPOP – cannot be used as only source of information
- uniparental markers significantly aid complex ancestry reporting but guidelines on how to use them are needed



React project

EDNAP

Summary of project so far

- Large consortium of more than 23 laboratories, where the primary purpose was to design experiments simulating typical casework circumstances; collect data and to implement Bayesian networks to assess the value (i.e., likelihood ratio) of DNA results given activity level propositions.

The ReAct project: Analysis of data from 23 different laboratories to characterise DNA recovery given two sets of activity level propositions

Peter Gill[a,b], Ane Elida Fonneløp[a,c], Tacha Hicks[d,e], Stavroulla Xenophontos[f], Marios Cariolou[f], Roland van Oorschot[g,h], Iris Buckel[i], Viktorija Sukser[j], Sunčica Papić[j], Siniša Merkaš[j], Ana Kostic[k], Angela Marques Pereira[l], Christina Teutsch[m], Christina Forsberg[n], Cordula Haas[o], Elizabet Petkovski[l], Fabian Hass[p], Jan Masek[q], Jelena Stosic[k], Yong Sheng Lee[r], Christopher Kiu-Choong Syn[r], Linda Groombridge[s], Marc Trimborn[p], Marilena Hadjivassiliou[f], Michelle Breathnach[t], Jana Novackova[q], Walther Parson[u,v], Petra Hatzer-Grubwieser[u], Sanna Pietikäinen[w], Simone Joas[m], Sascha Willuweit[p], Stefanie Grethe[x], Tamara Milićević[k], Therese Hasselqvist[n], Venus Kallupurackal[o], Vlastimil Stenzl[q], Staffan Jansson[n], Ingrun Glocker[x], Sarah Brunck[x], Karoline Nyhagen[a], Anne Berit Dyve Lingelem[a], Heli Autere[w], Devon Thornbury[y], Natalie Pedersen[y], Stephanie Fox[z], David Moore[aa], Gemma Escott[ab], Cathrine Bie Petersen[ac], Hans Jakob Larsen[ac], Rebecca Giles[ad], Paul Stafford Allen[ad], Ingo Bastisch[i,ae]

Key findings

- Can laboratory A share data with laboratory B?

Recovery varies between
200pg – 5ng

- Our latest work suggests around 10ng of DNA is deposited on a screwdriver when handled
- At best, around half is recovered
- At worst, around 98% is lost
- Median is 10% recovery

Back to the future (basics)

- Obviously, if we lose all the DNA from an extraction, we are not going to get much useful information
- In our pursuit of new methods and ever-increasing complexity of technology, have we forgotten something important?

Standardisation

- React project is the first to generate a large database of results: more than 2,700 samples at present
- New data are being accepted
- There are no restrictions on who joins in – i.e open to EDNAP members are everyone else
- However, there is more to do with standardisation, and this is also linked with normalisation of data
- React II will investigate a method where a lab can determine its recovery efficiency. This will be used as a factor which will help normalise data so that lab A can share data with lab B

The problem with publications

- Everyone has assumed that Transfer, Persistence and Recovery are lab independent:

$$p(TPR) = \underbrace{p(T) \times p(P)}_{lab\ \ independent} \times \underbrace{p(R)}_{lab\ \ dependent}$$

- But they are not
- So this has implications

Updated formula

$$p(TPR) = \underbrace{p(TP)}_{lab\ \ independent} \times \underbrace{p(R|TP)}_{lab\ \ dependent}$$

The problem with publications

- Data cannot be easily shared between labs to inform probabilities (because recovery rates are different)
- There is no overall standard for kind of data collected, or the method used to analyse
- Usually the data are not published, or are insufficient
- This also makes peer review very difficult, because we are effectively accepting data on trust
- Important to note that with the ReAct project, all data are published and furthermore all the results in the paper were created from the published data
- ReAct provides a model for the community to follow

Publications – bottom line

- Current publications represent the experience of the lab generating the paper
- The results may be interesting, but they cannot be directly used by other laboratories, as we have insufficient information available, lack of standardisation, and we work on the false premise that the probability of TPR is the same across all labs.

What is to be done

- Let’s recognise there is a problem
- Consensus view needed on standardisation of datasets
- Also, a method is needed to help normalise data between labs so data can be shared (in progress with ReAct II)
- Central databases needed – validation question of course – but we should follow example of STRidER
- In addition, we need to identify those Bayesian networks most used in casework
- So BNs, extraction efficiency and databases and the data used in them are closely linked

Summary

- In summary, the aim is to standardise data collection; define the raw data to be included as open-access data; define a series of open source Bayesian networks that can be used to capture the majority of casework. The ReAct project has published an extensive database which will hopefully kick-start the transition; there is an open invitation for any laboratory to contribute. It is envisaged that the ReAct database can follow the example already provided by STRider for collection of frequency databases. Ideally, it should eventually be placed under the auspices of a scientific society such as ISFG.
- Open to EDNAP members

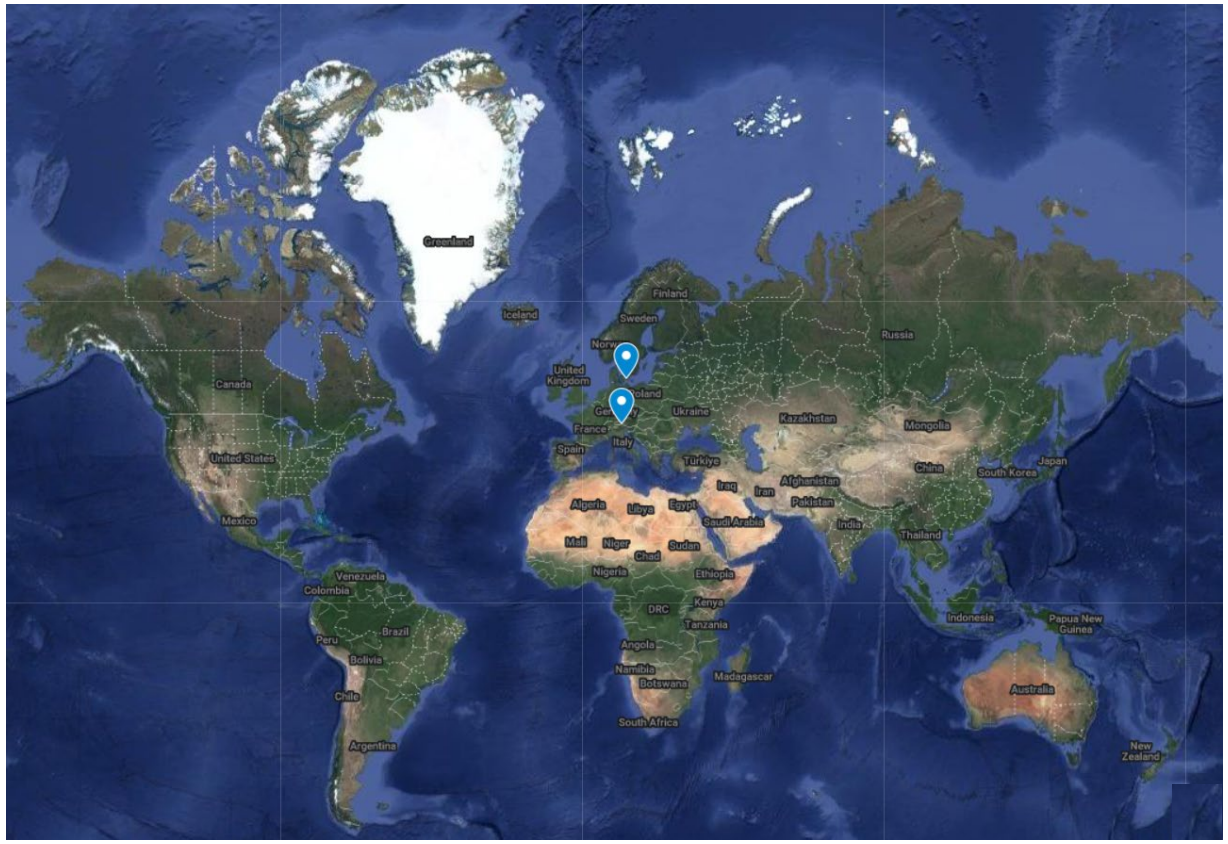
MITOMETRICS:

Characterisation of mitochondrial DNA heteroplasmy in hair shafts and its incorporation on likelihood ratio calculations

Vânia Pereira
Section of Forensic Genetics
Department of Forensic Medicine
University of Copenhagen

KØBENHAVNS UNIVERSITET

About the MitoMetrics initiative



To bring together group of scientists and practitioners working with mitochondrial DNA in the field of forensic genetics to investigate research questions dealing with the analysis and interpretation of mtDNA in forensic genetic casework.

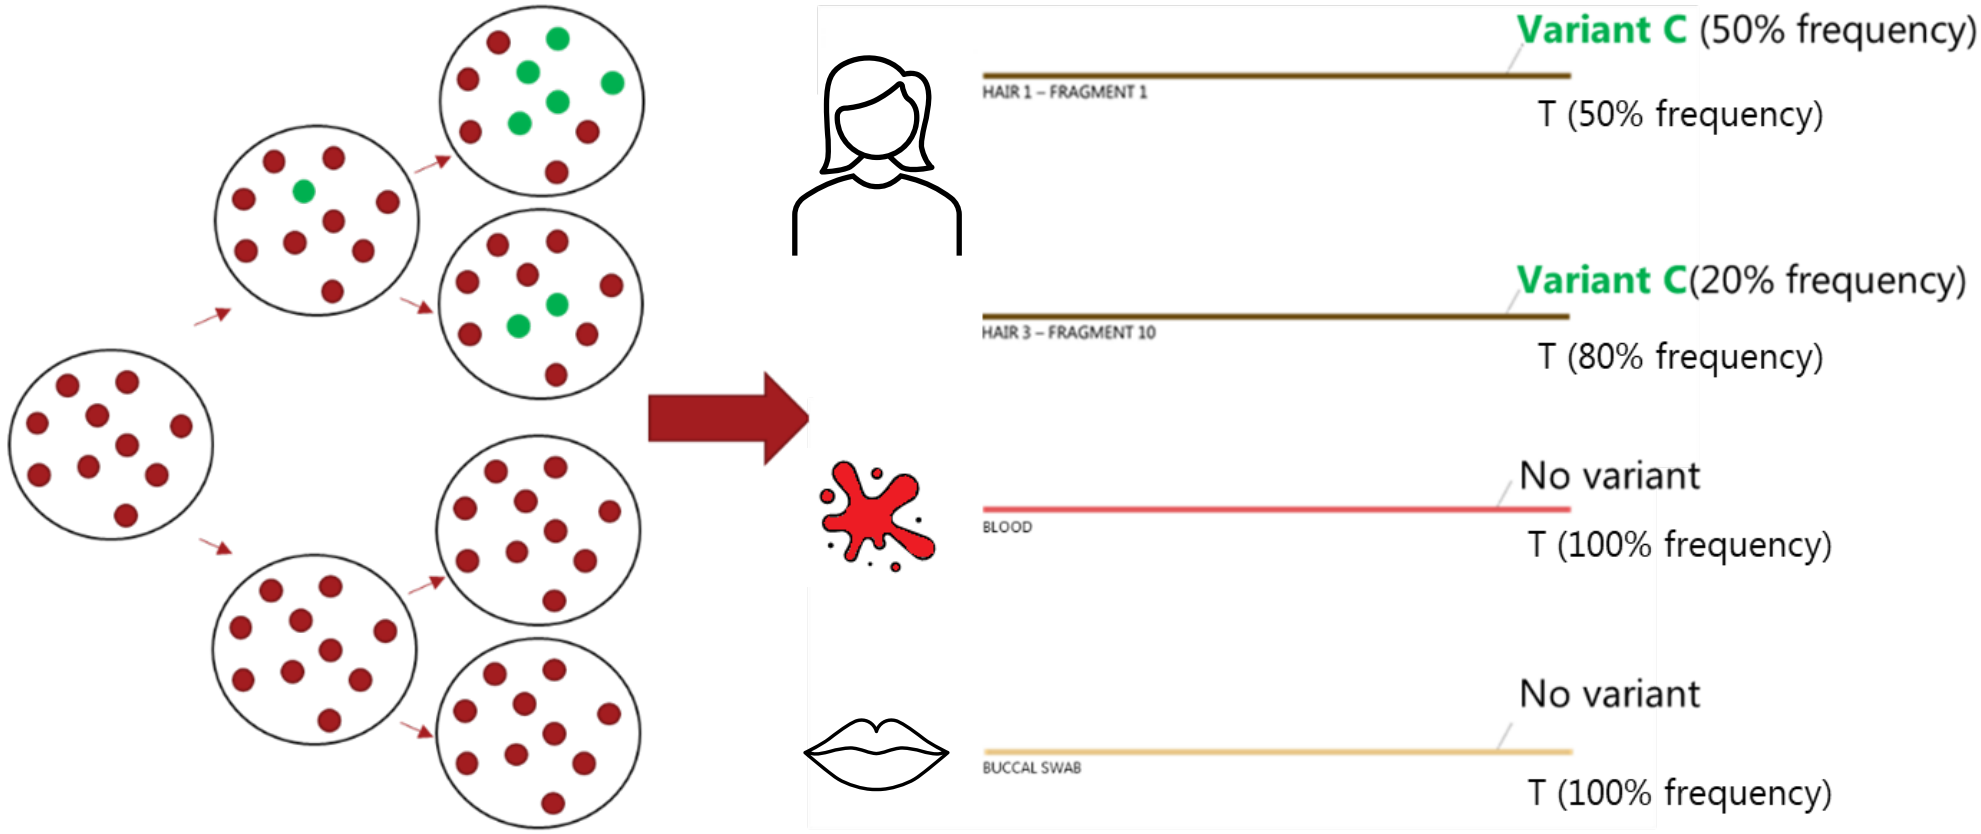
About the MitoMetrics initiative

Goal:
Improve the interpretation of mtDNA forensic evidence

Current forensic interpretation guidelines for mtDNA evidence are ruled-based conventions

Phylogenetic knowledge suggests that this approach is outdated and should instead be based on ground truth data.

mtDNA heteroplasmy

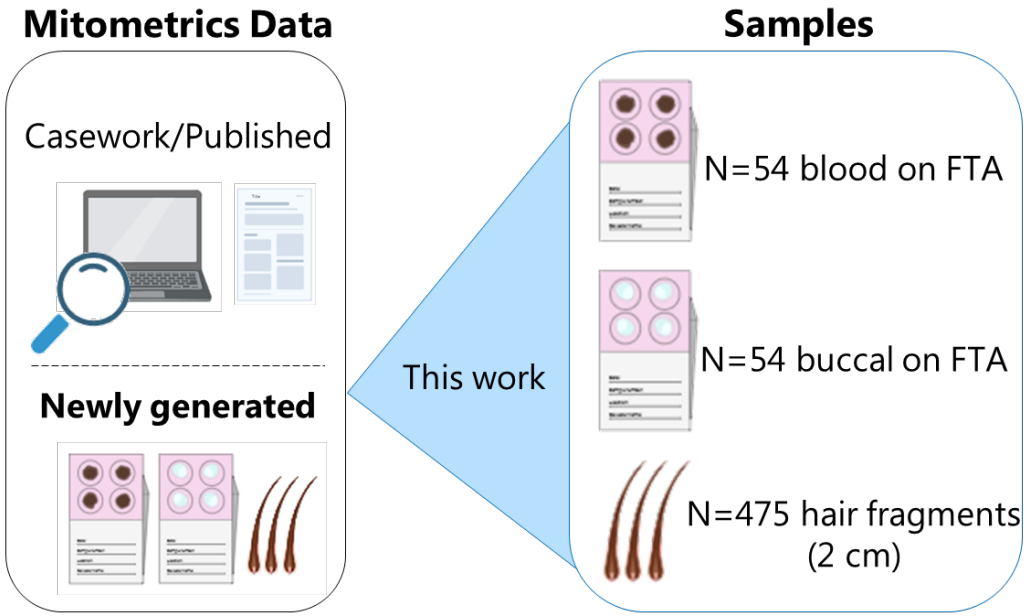


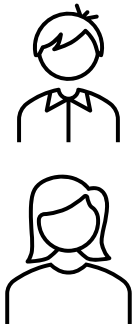
Aims

- Investigate heteroplasmy and the discrepancies in mtDNA profiles from hair shafts and reference samples from the same donor.

- Develop an initial model for calculating the weight of mtDNA-based evidence that incorporates the number of discrepancies observed.

Methods





- Blood drop on FTA card
- Buccal swab on FTA card
- 3 hairs, min. 3 fragments/hair

Methods

Mitometrics Data

Casework/Published

Newly generated

This work

Samples

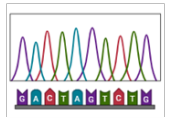
N=54 blood on FTA

N=54 buccal on FTA

N=475 hair fragments (2 cm)

Sequencing

N=120 Sanger (HVI+HVII)



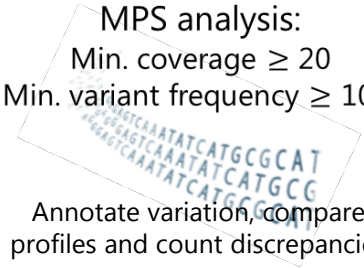
N=76 also MPS (HVI+HVII)

N=463 MPS (whole mtDNA)

N=55 iSeq N=410 Ion S5

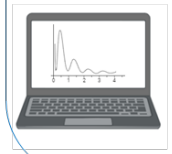
Data Analysis

MPS analysis:
Min. coverage ≥ 20
Min. variant frequency ≥ 10%



Annotate variation, compare profiles and count discrepancies

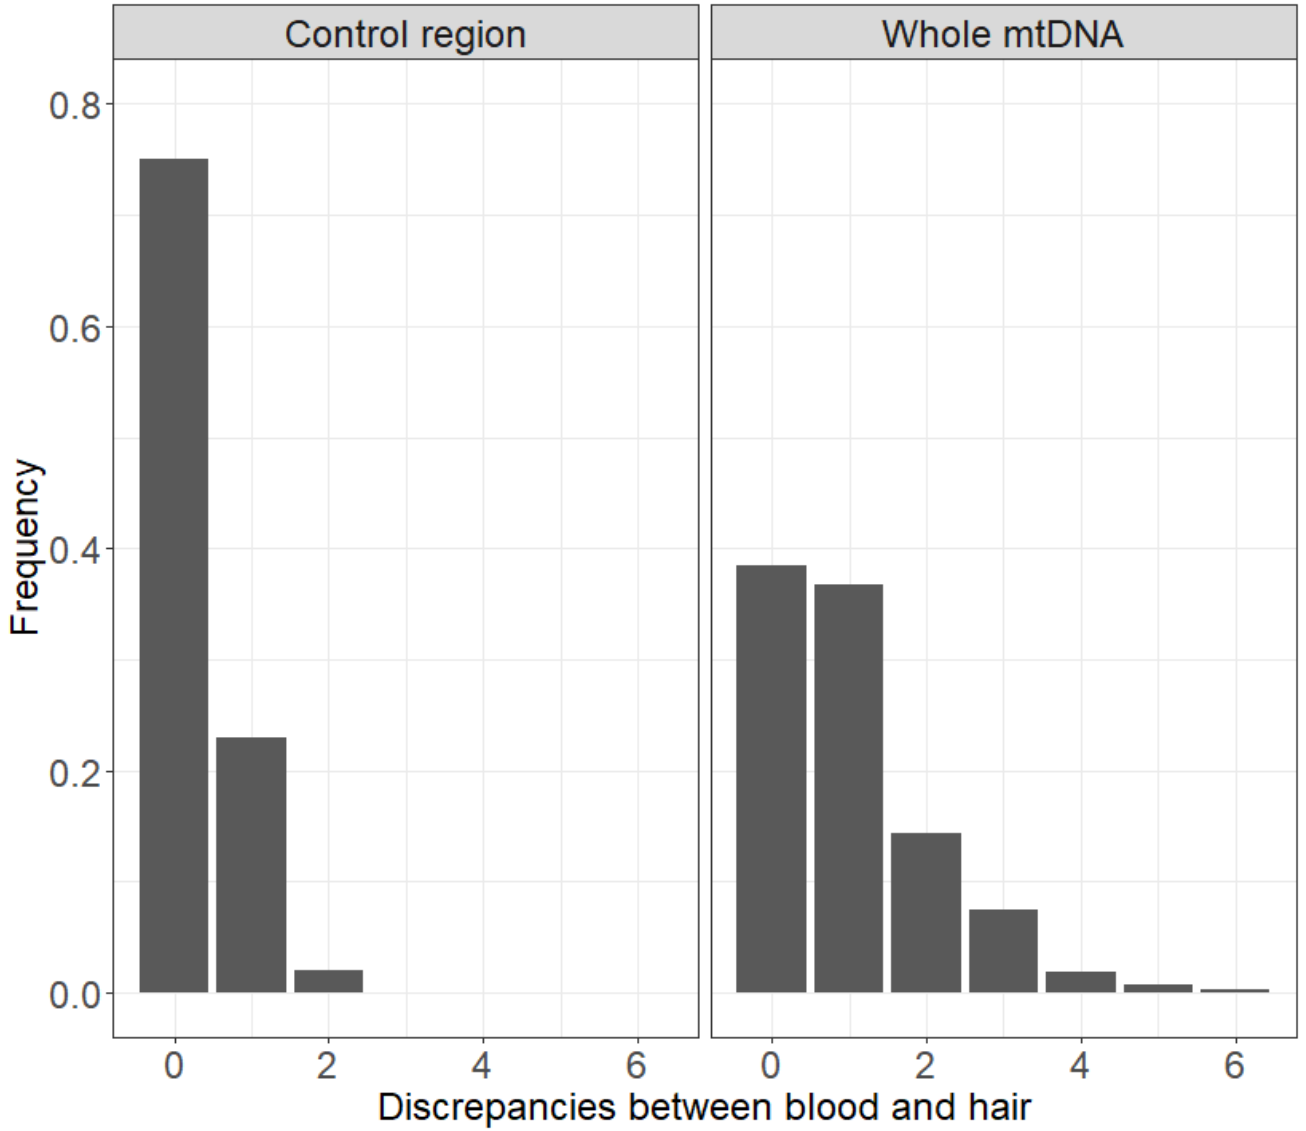
Statistical modelling:



Estimate Poisson for use in LR

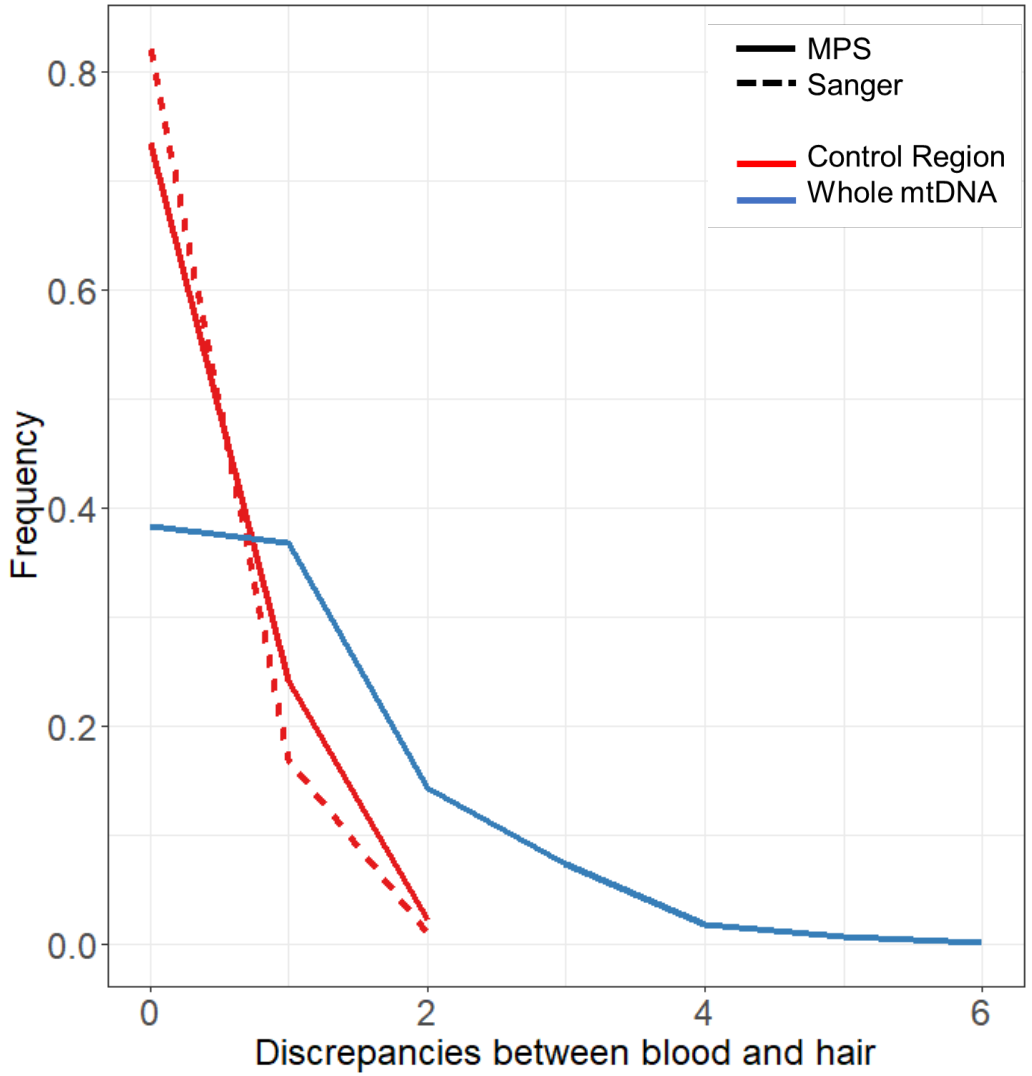
Heteroplasmic discrepancies between blood and hair

- In the control region, most comparisons between blood and hair had no discrepancies reported
- When considering the whole mtDNA molecule, some comparisons revealed 4 or more discrepancies, although these were not very common.



Statistical modelling of heteroplasmy

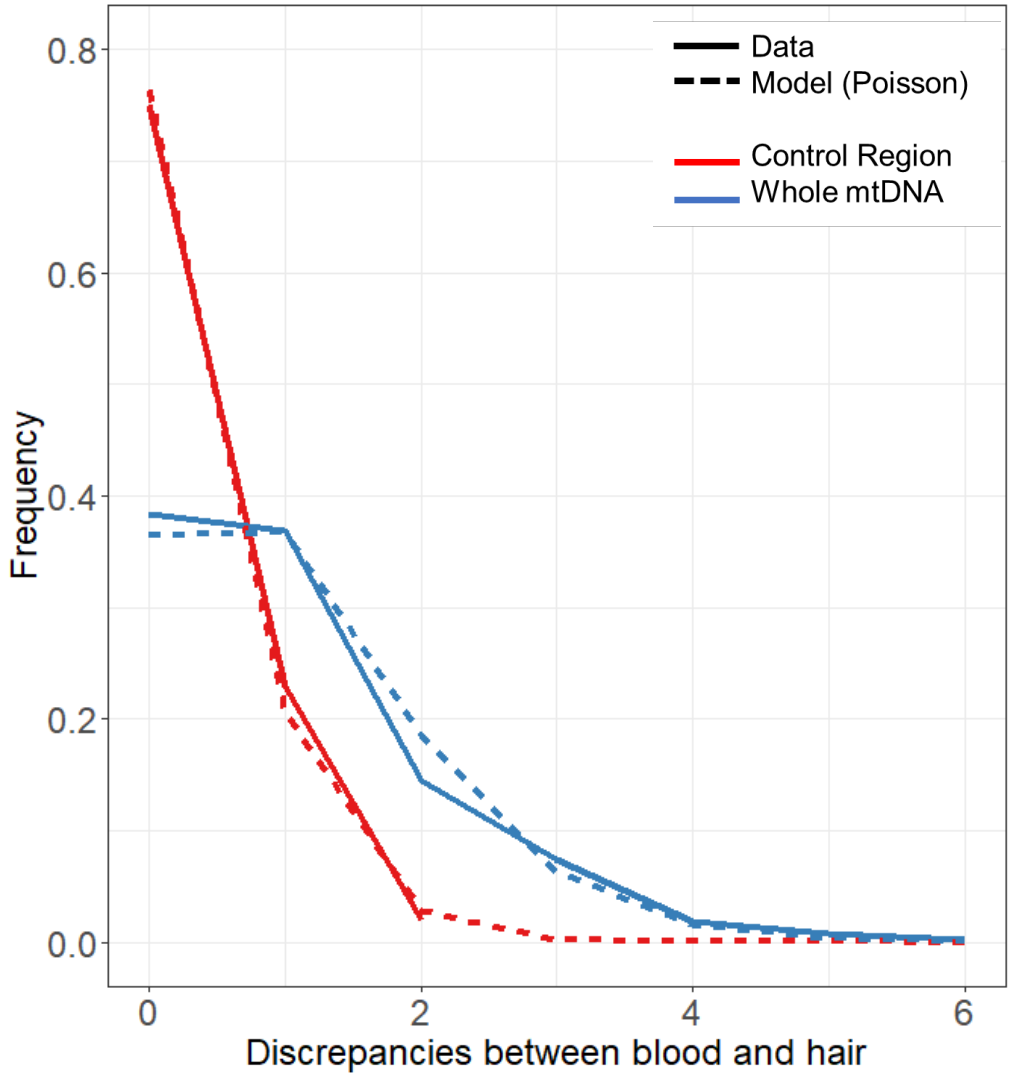
- Similar results were observed for Sanger sequencing and MPS data



Statistical modelling of heteroplasmy

- The frequency of observed discrepancies between reference and trace samples due to heteroplasmy resembled a Poisson distribution

- We can now model these events, and this information can be incorporated into a likelihood ratio (LR) calculation.



Incorporation of heteroplasmy in likelihood ratio calculations

- If the reference and the crime scene samples originate from different biological material from the same individual (blood reference and trace sample from hair, for example) we can then consider:

$$LR = \frac{P(D)}{P(X_Q)}$$

Where:

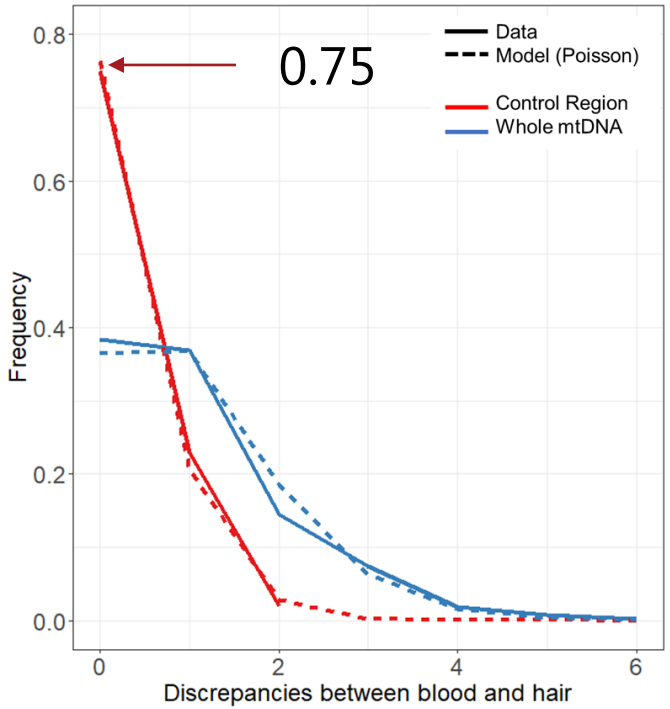
P(D): the frequency of heteroplasmic discrepancies between blood and hairs in a population

$P(X_Q)$: the frequency of the mtDNA profile of the trace in a population

Incorporation of heteroplasmy in likelihood ratio calculations

Assuming that:

- *P(D)* follows the model considering the mtDNA control region
- $P(X_Q)$ = 1/15782 = 6.34×10^{-5}, based on the size of the Westeurasian database of control region mtDNA profiles in EMPOP



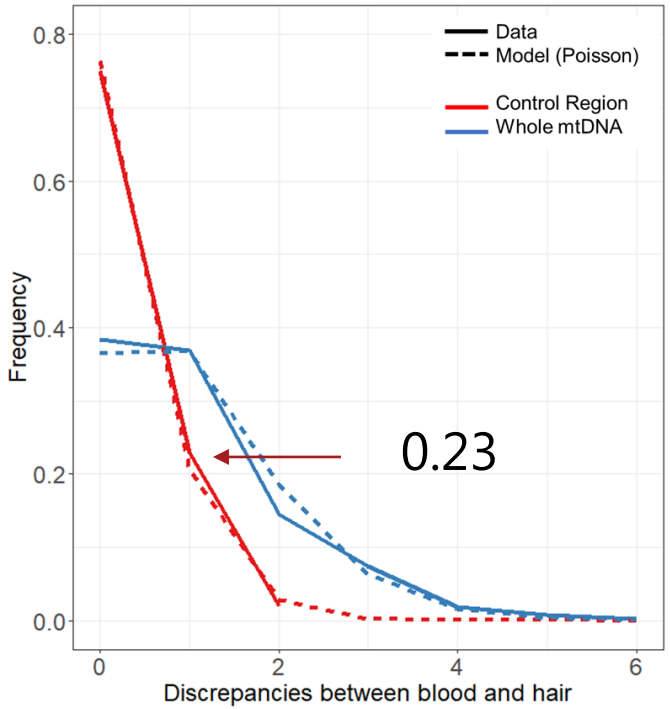
If D = 0 (no observed discrepancies between the profiles):

$$LR = \frac{P(D = 0)}{P(X_Q)}$$

Incorporation of heteroplasmy in likelihood ratio calculations

Assuming that:

- *P(D)* follows the model considering the mtDNA control region
- $P(X_Q)$ = 1/15782 = 6.34×10^{-5}, based on the size of the Westeurasian database of control region mtDNA profiles in EMPOP



If D = 1 (1 observed discrepancy between the profiles):

$$LR = \frac{P(D = 1)}{P(X_Q)}$$

Conclusions and Considerations

- Attempt to calculate the value of mtDNA-based evidence using LR, that considers the possibility of heteroplasmy in different tissues from the same donor.

- Other possible causes of discrepancies such as degradation, sequencing errors, and the effect of methodology used need to be further explored.

Conclusions and Considerations

Future work and further models should address:

→ How common/rare heteroplasmic positions (and the relative frequencies of the alleles) affect the LR

→ How heteroplasmy frequencies vary in and within different phylogenetic lineages

→ If mtDNA reference databases from different biological sources can be used to estimate the weight of the evidence in other tissues, or if any correction factors are needed
